

Visual Recovery Reference – Executive Summary

Client: Emirates Paints **Website:** <https://emiratespaints.com/> **Capture window (UTC):** 2026-09-02T14:22:16Z
→ 2026-09-03T00:32:42Z

Why this capture was conducted

The live website appears to depend on server-side cached pages: restoring the existing WordPress files and database to a staging environment does not reproduce what the public currently sees. Before any remediation, migration, cache purge, plugin update or infrastructure change, the publicly visible website was recorded as a timestamped, hash-verified reference so that the recovered website can later be checked against it.

What was captured

Every publicly reachable first-party page found through the homepage, navigation, footer, robots.txt, XML sitemap and internal links was rendered in a clean, unauthenticated Chromium browser at desktop (1440×900), tablet (768×1024) and mobile (390×844). For each page: above-the-fold and full-page PNG screenshots, the original response HTML, the rendered HTML, HTTP headers and redirect chain, page metadata, first-party assets, and safe interactive states (mobile menu, search panel, hover states). Publicly linked documents (PDF brochures/data sheets) were archived. Nothing on the production website was changed: no login, no form submission, no cache purge or bypass, one request at a time with delays.

Coverage

Metric	Value
URLs discovered	1286
HTML pages in scope	609
Pages fully captured at 3 viewports	609
Partially captured / failed	0 / 0
Public documents archived	46 of 46
Excluded (admin, account, cart, feeds)	567
Languages	en-US (606), en (2), und (1)
Evidence files with SHA-256 hash	10983 (2101 MB)
QA findings (high / medium / low+info)	99 / 388 / 2098
Cache status disclosed	45 pages HIT, 535 pages MISS
Browser	chromium 151.0.7922.34 (Playwright 1.62.0)

What the reference proves

That, during the capture window, an ordinary first-time visitor received the pages, text, images, navigation and layout shown in the screenshots and HTML files, with the recorded HTTP status, redirect and cache headers. Each file's SHA-256 hash in *evidence-register.csv* / *integrity/SHA256SUMS.txt* allows anyone to confirm the evidence has not been altered since capture.

What it does not prove

This Visual Recovery Reference records the publicly visible state of the website during the stated capture period. It is intended to support visual and public-functionality comparison following recovery. It does not constitute a complete WordPress source-code, database or application backup, and it does not independently prove that the underlying website was secure or fully functional at the time of capture. It also does not show what logged-in users, other devices or other cache nodes received, nor the behaviour of forms, search, store locator, wishlist or checkout, which were deliberately not exercised.

Important limitations

Pages served as a cache MISS were rendered by the current backend at the time of the visit and were then stored by the server cache as a normal side-effect of any visit – they show the backend's present output, which may differ from long-cached pages. Animated sliders, chat widgets and third-party embeds may vary between captures. Very tall pages are clipped at 16,000 px. Current visible defects (for example the product listing rendering empty behind the filter panel at the mobile viewport, where observed) are recorded, not repaired. See *capture-summary.md* and *exceptions.md* for the complete list.

Approval / sign-off

By signing below the client confirms that the captured reference (identified by the SHA-256 sums in *integrity/SHA256SUMS.txt*) represents the publicly visible website that the recovery project must restore, subject to the noted defects and limitations.

Name		Role	
Signature		Date	
SHA256SUMS.txt hash
